#### Abstract

The dominant sequence transduction models are based on complex recurrent or convolutional neural networks that include an encoder and a decoder. The best performing models also connect the encoder and decoder through an attention mechanism. We propose a new simple network architecture, the Transformer, based solely on attention mechanisms, dispensing with recurrence and convolutions entirely. Experiments on two machine translation tasks show these models to be superior in quality while being more parallelizable and requiring significantly less time to train. Our model achieves 28.4 BLEU on the WMT 2014 Englishto-German translation task, improving over the existing best results, including

## code

# Very nascent developer tooling

## web3 is beta-level web infrastructure

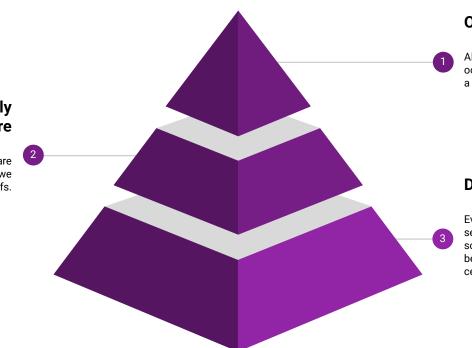

CENTRALIZED

**DECENTRALIZED** 

# Nodes VS Edges

#### Mathematically verifiable software

You need a way to audit the software to make sure that given x input we get y output. We need proofs.

#### Open data

All the events and transactions that occur in this app have to be written to a public blockchain or ledger

#### **Decentralized compute**

Every application lives on some server or is computed in ML case on some server. That server itself has to be provisioned and served in a censorship resistant way

## eVoting

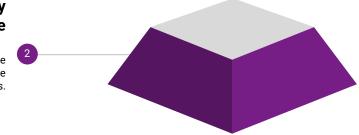

Privacy preserving open records.

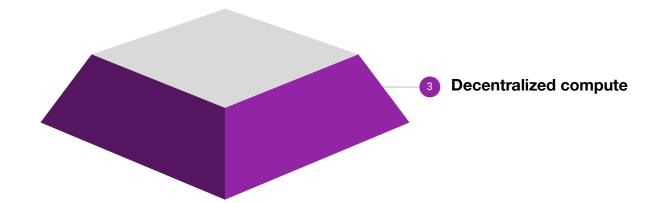

#### Mathematically verifiable software

You need a way to audit the software to make sure that given x input we get y output. We need proofs.

Can we improve ZK technology to allow for quick resolution proofs on complex ML training algorithms?

Do we bring the GPU to the data or do we move the data to the GPU?

# We need solutions at every level of that pyramid to truly unlock the promise of web3

## Thank you
